

What is underground gas storage?

There is a need to study the gas mixtures underground for storage. The concept of underground gas storage is based on the natural capacity of geological formations such as aquifers, depleted oil and gas reservoirs, and salt caverns to store gases.

What are the different types of underground natural gas storage facilities?

We distinguish between two types of underground natural gas storage facilities: porous rock storage facilities are natural reservoirs in porous rock in which the natural gas can be stored in very large quantities, similar to a stable sponge.

What is a natural gas supply system?

The natural gas supply system in this model consists of import facilities, cross-provincial transmission pipelines and storage facilities, whilst transmission pipelines inside a province are neglected. China's natural gas import has been increasing fast in recent years, and the external dependent degree has exceeded 40%.

What is energy storage system?

The energy storage system is regarded as the most effective method for overcoming these intermittents. There are a variety of ESSs that store energy in various forms. Some of these systems have attained maturity, while others are still under development.

How does a gas storage facility work?

The interactive graphic describes the individual surface and underground components of the storage facility in detail. The transmission system transports the gas to be stored from the production reservoirs or import terminals, sometimes over several thousand kilometers, to the storage facility.

Why do we store gas in underground storage facilities?

Today, gas consumption is subject to large seasonal fluctuations between summer and winter as well as short-term changes in demand when gas is traded. By storing gas on a large scale in our underground gas storage facilities, we balance these out.
