

How do you turn a wind turbine if you don't use water?

Using steam is the best way to do this - as long as you can make heat, you can use that heat to boil water and the steam to turn a turbine. There are some methods that don't use water - some solar panels just make electricity directly and wind turbines use wind rather than steam - but for most other fuel sources still use steam.

How does turbine inlet temperature affect power output?

The increase in turbine inlet temperature means an increase in superheat at constant inlet steam pressure and condenser pressure gives a steady improvement in the power output of the turbine. Raising the inlet steam temperature also reduces the wetness of the steam in the later stages of the turbine and improves the power output of the turbine.

How does a steam turbine generator work?

A steam turbine generator works by heating water to extremely high temperatures until it is converted into steam, then the steam energy is used to rotate the blades of a turbine to create mechanical or rotational energy. This rotational energy caused by the high pressured steam turbine is used to generate electricity from an attached generator.

What factors affect the performance of a turbine?

Turbines are designed for a particular operating conditions like steam inlet pressure, steam inlet temperature and turbine exhaust pressure/exhaust vacuum, which affects the performance of the turbines in a significant way. Variations in these parameters affects the steam consumption in the turbines and also the turbine efficiency.

Why do steam turbines have a low efficiency?

Wear of contacting surfaces may result in increased clearances, resulting in reduced efficiency through steam leakage. The HP and IP cylinders in steam turbines operate at high efficiencies and therefore the main opportunity for performance improvement comes from increasing the steam inlet temperature.

Why do steam turbines have low frequency cycles?

Low frequency cycles occur due to start-up and shut-down of the turbine. This damage mode is becoming increasingly important as the operation of steam turbines evolves to accommodate the increased exposure of electricity supply to renewables, particularly wind power.

Very High-Pressure Steam Turbine; Supercritical Pressure Steam turbine; According to Exhaust conditions ... Too-high temperatures can also lead to creep deformation in the rotating blades. ...

Modern power plants work with supercritical "steam", basically you can raise water to a high enough temperature that its just this hot dense mix and not really liquid or steam and you can ...

The small steam turbine generates up to 40 percent more electricity with the same fuel input than conventional steam turbines in the output range up to 300 kW. Due to the high efficiency and ...
